*In Re: GE-Pittsfield/Housatonic River Site/Rest of River Portion
Petition to Town of Lee Board of Health by HRI,
Notification, and Request for Assistance.*

Dear Mr. Kilborn:

The purpose of this letter is two-fold. First, this letter responds to your letter, dated June 22, 2022, addressed to Jeremia Pollard, Esq. Attorney for the Town of Lee, Massachusetts regarding a petition of the Housatonic River Initiative (“HRI”) dated June 3, 2022 to the Lee Board of Health (*hereinafter* “LBOH”) of Massachusetts (the “Petition”). The Petition requests that the LBOH hold adjudicatory hearings to determine whether an Upland Disposal Facility (“UDF”) to be constructed in the Town of Lee to facilitate the cleanup of the Housatonic River presents “a health impact to the residents of Lee.” (Letter Kilborn to Pollard). Second, this letter requests EPA’s assistance to LBOH on a matter decided by LBOH on September 22, 2022.

First: Response to Your Letter to Jeremia Pollard, Esq.

You assert in your response to Attorney Pollard that UDF is safe, effective, and protective of human health and the environment and that “EPA takes no position regarding the request for a hearing because...the hearing is a matter of state and municipal law, not federal law.” LBOH agrees with you that the requested hearing is a matter of State Law. You erred in concluding that the requested hearing is a matter of municipal law.

MGL c. 111, §§ 31 and 143 provide that Boards of Health may make reasonable health regulations. Section 31 provides that Boards of Health may make reasonable health regulations. §143 prohibits the establishment in a city or town of trades which may be harmful to the public, "except in such a location as may be assigned by the board of health...after a public hearing has been held thereon.”

Thus, the legal standard that governs whether or not a Board of Health in Massachusetts can bar an activity in a town is simply whether the particular activity “may be harmful to the public”. *Id.*

The legal standard that governs a finding by EPA that a particular activity is “safe, effective, and protective of human health and the environment” is governed by a myriad of considerations including mortality risk evaluations, cost-benefit analysis, assignment of value of a statistical life such as 0.7 to 12.9 million dollars etc. (EPA publication: <https://www.epa.gov/environmental-economics/mortality-risk-evaluation#bca>). The two standards are not compatible because as admitted by you in your letter to Attorney Pollard, “...the construction of the UDF ...will facilitate the River’s cleanup...”*Id.* Whether or not the UDF will facilitate the river clean up, or for that matter whether the risk-cost analyses conducted by EPA favors building the UDF are not issues that need to be addressed by the LBOH, as its only concern is whether or not the UDF will present a risk to the health of the inhabitants of Lee and adjacent communities.

In your letter to Attorney Pollard you cite a number of court decisions establishing that EPA in a CERCLA action preempts **municipal** ordinances, failing to cite a single case in which a CERCLA action has preempted a Board of Health decision in Massachusetts governed by MGL c. 111, §§ 31 and 143. These CERCLA citations are irrelevant to the issue at hand. You ignore in your letter to Attorney Pollard the decision of the Supreme Judicial Court of Massachusetts, establishing that neither the State nor Federal Agencies have the power to preempt a decision of a BOH in Massachusetts issued under MGL c. 111, §§ 31 and 143.

The Supreme Judicial Court of Massachusetts in *Arthur D. Little v. Commissioner of Health of Cambridge* 395 Mass. 535; 481 N.E.2d 441; 1985 Mass. LEXIS 1720(1985) dealt extensively with the lack of preemption powers of State and Federal Agencies over decisions of Boards of Health on matters related to health risks to the residents of a Town. I quote here the preemption issue analysis of the Supreme Judicial Court of Massachusetts in *Arthur D. Little*, which you ignored.

First, "[p]reemption is not favored, and State laws should be upheld unless a conflict with Federal law is clear." *Attorney Gen. v. Travelers Ins. Co.*, 385 Mass. 598, 602 (1982) (*Travelers I*), vacated, 463 U.S. 1221 (1983), reaffirmed, 391 Mass. 730 (1984), aff'd sub nom. *Metropolitan Life Ins. Co. v. Massachusetts*, 471 U.S. 724 (1985). See *Commonwealth v. McHugh*, 326 Mass. 249, 265-266 (1950); *Exxon Corp. v. Governor of Md.*, 437 U.S. 117, 132 (1978). State law is not preempted merely by reference to some vaguely defined Federal policy, or on the grounds that Congress has enacted a statute which is tangentially relevant to the subject at issue. Instead, the plaintiff here is obligated to show preemption "with hard evidence of conflict on the basis of the record evidence in this case." *Grocery Mfrs. of Am., Inc. v. Department of Pub. Health*, 379 Mass. 70, 81-82 (1979), quoting *Kargman v. Sullivan*, 552 F.2d 2, 6 (1st Cir. 1977). Generally speaking, "a finding of no preemption is regarded as preferable because Congress can overrule it by appropriate legislation, while a finding of preemption cannot be changed by the states." *Agency Rent-A-Car, Inc. v. Connolly*, 686 F.2d 1029, 1038 (1st Cir. 1982). See *Pacific Gas & Elec. Co. v.*

State Energy Resources Conservation & Dev. Comm'n, 461 U.S. 190, 216 (1983).

Secondly, the Court argued that the Supreme Judicial Court of the Commonwealth and the United States Supreme Court have been particularly reluctant to overturn State laws which are “deeply rooted in local feeling and responsibility.” *Travelers I*, *supra* at 611, quoting *San Diego Bldg. Trades Council v. Garmon*, 359 U.S. 236, 243-244 (1959). *Massachusetts Elec. Co. v. Massachusetts Comm'n Against Discrimination*, 375 Mass. 160, 174 (1978). **This principle applies with special force to laws designed to protect the public health and welfare**, a subject of “particular, immediate, and perpetual concern” to any municipality 6 *E. McQuillin, Municipal Corporations* § 24.01 (3d ed. Rev. 1980). In fact, according to an early decision of the Massachusetts Supreme Judicial Court, *Vandine, petitioner*, 6 Pick. 187, 191 (1828), “[t]he great object of the city is to preserve the health of the inhabitants.” Accordingly, municipal health and safety regulations, such as that at issue here, carry a heavy presumption of validity and are only rarely preempted by Federal law. *Travelers I*, *supra* at 612. See *Malone v. White Motor Corp.*, 435 U.S. 497, 513 n.13 (1978). “The States traditionally have had great latitude under their police powers to legislate as ‘to the protection of the lives, limbs, health, comfort, and quiet of all persons.’” *Metropolitan Life Ins. Co. v. Massachusetts*, 471 U.S. 724, 756 (1985), quoting *Slaughter-House Cases*, 16 Wall. (83 U.S.) 36, 62 (1873). *Huron Portland Cement Co. v. Detroit*, 362 U.S. 440, 442-443 (1960). (*emphasis added*).

Second: Notification and Request for Assistance

LBOH has accepted the request by citizens of Lee to conduct an adjudicatory hearing in the near future to conclude, on the basis of expert testimony, whether or not UDH presents a health risk to the residents of Lee and adjacent communities. EPA will be notified within the next few weeks of the location of the adjudicatory hearing. LBOH will decide after the hearing takes place, under the preponderance of the evidence, whether or not the construction and operation of the UDF presents or does not present a risk of health to the residents of Lee and adjacent communities and will either ban or allow the construction of the proposed UDF.

EPA could be of assistance to LBOH in reaching a final decision on the matter since it has acquired information that resulted in EPA concluding that the projected location for the UDF is safe, effective, and protective of human health and the environment.” *Id.* LBOH would be interested in establishing whether this finding might be sufficient to satisfy the standard required by MGL c. 111, §§ 31 for a finding that UDF does not present a risk of health to the residents of Lee and adjacent communities. EPA can contribute scientifically to such a possible eventual finding by supplying EPA experts who can testify to the basis used by EPA to reach its decision.

LBOH is aware that, during the Obama Administration, EPA rejected the location of UDF in Lee. Yet, a few years later, EPA reversed itself under the Trump administration and reached the current conclusion that UDF is safe. LBOH does not want to believe that EPA change of position was merely a political decision that ignored the health of the residents of Lee. Clarification of the reversal by EPA is needed. LBOH requests that EPA provide LBOH the complete risk/benefit and cost benefit analyses that supported both EPA contrary conclusions. It is our understanding from published reports that HRI and others have asked EPA under a FOIA request to provide this information only to be told by EPA that it will cost the petitioners more than \$39,000 dollars in copying costs to provide the requested information. These extraordinary copying costs on a critical issue of health to Lee’s residents leads to the suspicion that EPA is hiding the reasons as to why it reversed itself on the issue of the UDF from one federal administration to another.

There is no issue more important for LBOH to consider at the adjudicatory hearing than the possibility that UDF might not be able to prevent leaks of PCBs from the UDF which will contaminate the Housatonic River, the town of Stockbridge’s **marble aquifer** or the homes of residents of Lee and adjacent communities.

David J. De Simone, Ph.D., a geologist with enormous knowledge and experience and co-recipient of the 2020 EPA Region 1, Environmental Merit Award for Scientific Research, has made available to LBOH his research and conclusions regarding the proposed UDF. His report, curriculum vitae, and publications are attached to this letter. His unequivocal conclusions are quoted here directly from his Report:

My primary concern for this site as a landfill is that a leak in the liner and leachate collection system will eventually occur; then, leachate will have no natural sediment barrier to flow in the subsurface. EPA has stated **“First, even the best liner and leachate collection systems will ultimately fail due to natural deterioration...”(53 Federal Register 33345, August 30, 1988).** The sand and gravel aquifer will become contaminated and leachate will easily infiltrate underlying bedrock. This is a poor site for a landfill (emphasis here only).

The bottom line is the geology of the proposed PCB landfill location is very likely to result in leachate contamination of surficial and bedrock aquifers if leachate penetrates the landfill liners. Based upon site geology, PCB disposal in a landfill in this location is a very poor choice that may result in PCB contamination of the sand and gravel aquifer and the underlying Stockbridge marble aquifer. (Simone’s Report attached)).

LBOH would very much like to learn the factors used by EPA for EPA’s cost/benefit and risk benefit analyses that led it to conclude that the proposed UDF is safe, in spite of Dr. De Simone’s conclusions.

Please let LBOH know by Friday October 7th at 5 P.M whether EPA will or will not acquiesce to the simple requests of LBOH enumerated in this letter.

Failure of EPA to provide the information requested in this letter and failure to participate at the forthcoming adjudicatory hearing will be taken by the LBOH, and for that matter by any court, as a presumption that EPA erred in concluding that the UDF is safe.

Thank you for the attention you will give to this letter.

Sincerely,

By Attorney for the Lee Board of Health of Massachusetts.

Cristóbal Bonifaz

Geological Evaluation of the Proposed Woods Pond Landfill Site, Lee, MA

Introduction: I reviewed documents and evaluated the surficial and bedrock geology for the proposed PCB landfill site north of Willow Hill Road and south of Woods Pond, Town of Lee, MA. My work scope was to address these parameters the nature and stratigraphy of glacial sediments and how this impacts infiltration and lateral movement of ground water beneath the PCB landfill site. Does the landfill site have geological characteristics that weigh against using the site as a PCB landfill? How likely is it that there is natural sediment overlying bedrock beneath the sand and gravel shown on surficial maps that is low in permeability - hydraulic conductivity - and can inhibit infiltration of leachate from inevitable leaks? Double composite liners and leachate collection systems should be expected to fail and I wanted to see what might happen to leachate that infiltrated the site below the liners.

Surficial geology: My analysis of surficial geologic maps of the East Lee 1:24,000 quadrangle by Stone and DiGiacamo-Cohen (2018) and Holmes (1962) indicates the proposed PCB landfill site lies in an area of ice contact stratified drift that is usually not associated with either thick, impermeable till sediment or glaciolacustrine silt-clay of any appreciable thickness or lateral continuity. Ice contact stratified drift is a variable mixture of sand and gravel, sediment that is highly permeable.

The Holmes (1962) map identifies the sediment at the proposed PCB landfill site as “Qcd” - ice contact stratified drift. Holmes described the sediments as kettled, collapsed or eroded glaciofluvial deposits - deposition from melt water and/or meteoric water in contact with melting glacial ice. Such environments may have sediments deposited beneath, within and atop glacial ice. More often than not, the ice itself may have become stagnant and even detached from the active glacial margin. Melting of glacial ice syn-depositionally and post-depositionally causes the sediments to collapse and form a hummocky, kettled landform. If the depositional environment can be associated with a slowed or paused retreat of a glacial margin in a valley, the landform may be identified as a kame moraine, a

cross valley accumulation of ice contact sediment associated with a glacial margin. The term kame moraine was defined by Frank B. Taylor during his time as a glacial geologist with the USGS in the early decades of the 20th century. Taylor worked extensively in the western Berkshires and southern Vermont, mostly in the Hoosic River drainage basin. He coined the term “kame moraine” to describe ice contact landforms composed predominantly of glaciofluvial sediments but representing deposition in an environment similar to that of a till moraine. My map review indicates the kame and kettle landforms at the proposed landfill site do not represent a kame moraine. Rather, it appears to be part of a larger area of the valley floor where ice became stagnant and blocks of ice were detached from an active ice front. Woods Pond, thus, represents a large kettle pond. Kame moraines have a greater chance of having some till within the sediment accumulation. Since this is not the case, it is more likely the sediments have little or no till beneath the sand and gravel.

Holmes’ map identifies exposures of sediment in the landfill areas as boulder gravel, cobble gravel, cobble sand and pebble sand. These are all very typical of ice contact stratified drift where the sediment texture can vary highly over a short lateral or vertical distance. In other words, sediments are rarely arranged in neat, horizontal layers but rather form a landform with abrupt and sharp sediment texture changes. This makes prediction of hydraulic properties in these sediments especially difficult to incorporate into ground water flow models, for example. Such models often assume “layer cake” stratigraphy with homogeneous sediment textures within layers. Glaciofluvial ice contact sediments almost never meet this assumption. Thus, modeled ground water flow must be viewed cautiously, at best. Note, these sediments are among the most permeable we find in glacial environments. They are the worst natural sediments to use for a PCB landfill because they allow easy migration of contaminants in the subsurface.

Stone & DiGiacamo-Cohen (2018) identify the same deposit as stratified coarse glaciofluvial sediments:

“Coarse deposits consist of gravel deposits, sand and gravel deposits, and sand deposits, not differentiated in this report. Gravel deposits are composed of at least 50 percent gravel-size clasts; cobbles and boulders predominate; minor amounts of sand occur within gravel beds, and sand comprises a few separate layers. Gravel layers generally are poorly sorted, and bedding commonly is distorted and faulted due to postdepositional collapse related to melting of ice. Sand and gravel deposits occur as mixtures of gravel and sand within individual layers and as layers of sand alternating with layers of gravel. Sand and gravel layers generally range between 25 and 50 percent gravel particles and between 50 and 75 percent sand particles. Layers are well sorted to poorly sorted; bedding may be distorted and faulted due to postdepositional collapse. Sand deposits are composed mainly of very coarse to fine sand, commonly in well-sorted layers. Coarser layers may contain up to 25 percent gravel particles, generally granules and pebbles; finer layers may contain some very fine sand, silt, and clay.”

“Sorted and stratified sediments composed of gravel, sand, silt, and clay (as defined in the particle-size diagram, figure 12, below), deposited in layers by glacial meltwater. These sediments occur as four basic textural units: gravel deposits, sand and gravel deposits, sand deposits, and fine deposits. On this surficial geologic map, gravel deposits, sand and gravel deposits, and sand deposits are not differentiated and are shown as Coarse Deposits where they occur at the land surface. Fine Deposits also are shown where they occur at the land surface. Textural changes occur both aerially and vertically (fig. 9); however, subsurface textural variations are not shown on this map.”

This description is basically the same as Holmes older description of the deposits. What's changed is the nature of the map units used by the USGS. The current map units focus on the sediment types and origins - ice contact glaciofluvial for example - rather than any landforms the sediments may be associated with such as kame and kettle. It's a conservative approach to labelling map units and makes for a more accurate and functional map with fewer interpretations of the landform origins on the part of the mapper. This is a “safer” approach since so many different mappers may contribute to a statewide mapping program as was recently completed in MA.

surficial geology conclusions; The conclusion drawn from the surficial map analysis is that the proposed landfill site contains highly permeable sand and gravel sediments. These sediments vary texturally over both lateral and vertical distances as shown by Holmes descriptors for the sediments just within the landfill areas alone. There is no indication of till present beneath the sand and gravel in significant thickness or continuity to present a barrier to subsurface flow of contaminants. Ice contact stratified drift sediments are very poor locations for landfills due to their high permeability. My primary concern for this site as a landfill is that a leak in the liner and leachate collection system will eventually occur; then, leachate will have no natural sediment barrier to flow in the subsurface. EPA has stated “First, even the best liner and leachate collection systems will ultimately fail due to natural deterioration...” (53 Federal Register 33345, August 30, 1988). The sand and gravel aquifer will become contaminated and leachate will easily infiltrate underlying bedrock. This is a poor site for a landfill.

Bedrock geology: Ratcliffe (1985) mapped the bedrock geology of the East Lee, MA quadrangle. The proposed PCB landfill area is underlain by Stockbridge Formation carbonate rock, chiefly dolomitic marble. This rock contains fractures or joint planes that are migration pathways for ground water and any contaminants based upon my own experience as a mapper where this formation occurs. Further, enlargement of fractures/joints due to dissolution in carbonate bedrock provides pathways for very rapid movement of ground water in the subsurface. Thus, a PCB landfill sited in the proposed location might allow leachate to enter bedrock and flow toward the Housatonic River to the west. Once any leak occurs, the natural gravel and sand substrate - highly permeable sediment - will have pose no impermeable natural barrier to inhibit flow into the

underlying marble bedrock. Till is not likely present in a sufficiently thick and continuous layer to inhibit downward flow of the leachate.

bedrock geology conclusion; The Stockbridge marble is a rock that contains fractures/joints that may allow very rapid ground water flow along discrete pathways. Further, dissolution of rock along these fractures/joints makes this an extremely poor choice for bedrock beneath a PCB landfill.

Existing landfills: The 2 closed landfills along Willow Hill Road are identified (MA DEP, 2017) as unlined and capped in 1997 and 1999. A capped landfill minimizes infiltration of meteoric water through the landfill contents into the the water table aquifer and bedrock aquifer(s) below. Unlined landfills have no protection from leachate entering surficial aquifers and/or bedrock aquifers below the landfilled material. Both landfills were situated in the mapped ice contact stratified drift sediments. Both landfills likely took advantage of existing depressions in the land surface that were a result of historic gravel and sand mining. The depth of mining was often limited by the water table in the gravel and sand sediments.

Geological understanding of these glaciofluvial depositional environments is that these sediments are often deposited directly on bedrock with little or no low permeability till sediments to act as an aquiclude to protect the underlying bedrock aquifers. The overburden sediments are often a thick and highly permeable overall package that represent an unconfined aquifer and this sediment is likely directly atop fractured and dissolved marble. Such locales were often chosen for landfills primarily due to expediency and not based upon geology.

The 2 neighboring landfills have been capped, and both were landfills for non-hazardous waste. Yet, recent ground water monitoring results from both landfills reflect that they are leaching hazardous chemicals into the ground water. These results make it even more clear that Willow Hill Road is one of the poorest geological locations for a new PCB landfill.

Summary & suggestions: The surficial and bedrock geology described in the above discussion represents what we professors would tell our students in an environmental geology course as a textbook example of where not to locate a landfill. This location is underlain by highly permeable sediment of sand and gravel texture. Infiltration of PCB leachate through these sediments would not be inhibited by any impermeable sediment prior to reaching marble bedrock. The marble would allow rapid migration of contaminants. Very rapid migration of contaminants along fractures/joints enlarged by dissolution would pose an even greater risk of contamination at further distances from the landfill.

The surficial geology consists of high permeability sand and gravel sediments with unpredictable lateral and vertical stratigraphic continuity. Leachate that infiltrates through the designed barriers into this sediment will flow downward through the sand and gravel into the bedrock aquifer below.

The bedrock consists of Stockbridge carbonate rock that is susceptible to dissolution along vertical fractures and along bedding planes. Dissolution causes

very rapid ground water flow along discrete pathways through fractures and along bedding planes. Indeed, ground water flow in conduits - including caverns - is possible if they are present in the subsurface.

The bottom line is the geology of the proposed PCB landfill location is very likely to result in leachate contamination of surficial and bedrock aquifers if leachate penetrates the landfill liners. Based upon site geology, PCB disposal in a landfill in this location is a very poor choice that may result in PCB contamination of the sand and gravel aquifer and the underlying Stockbridge marble aquifer.

Background Information on the Author:

I am a geoscientist/environmental scientist engaged in contract, academic and applied research in geomorphology, geoarchaeology, hydrogeology and environmental geology. Contract work as project geomorphologist for archaeology investigations takes me on projects in the Northeast. My surficial geologic mapping occurs primarily in New York & Vermont for STATEMAP research and for understanding contaminant distribution & migration through glacial and post-glacial sediments.

Throughout my professional academic career as a lecturer and visiting/adjunct professor, I've taught geoscience and environmental science at Williams College, RPI, Bennington College and The College of Saint Rose with a keen eye toward the application of these sciences to practical situations. I have attained a respected status as an expert in the glacial geologic history of upstate NY and adjacent Vermont demonstrated by maps & publications over many decades and by lectures given to colleagues and the public.

Most recently, I mapped the surficial geology of PFOA contaminated regions in Hoosick Falls and Petersburg, NY, and in Bennington and Rutland, VT. The Vermont work was performed for the VT Geological Survey. My research mapping has covered the Hudson-Champlain lowlands, Adirondack and Catskill Mountains, and portions of VT.

I have been a Visiting Scientist for the National Park Service, part of the GSA-NPS Geoscientists-in-the-Parks program. In 2015, I generated both surficial & bedrock geologic maps of 4 quadrangles in the Hudson Valley that encompass the Saratoga National Historical Park, a colonial era battlefield. Past mapping in the Catskills includes the Phoenicia & Thiells quadrangles completed for the NY Geological Survey.

Surficial mapping in VT over decades and the evolution of GIS map layers I developed has become the model for mapping in VT and elsewhere. I've conducted geomorphology research in CO, MT, WY & AK in glaciated, formerly glaciated and periglacial terrain. Cultural Resource Management experience is a growing part of my work along countless rivers, streams and reservoir shores and rights-of-ways.
